

**Teachers Teaching Teachers: The Role of Workplace Peers on Financial  
Decisions  
Internet Appendix**

This internet appendix is divided into two sections. The first section provides a detailed description of the estimation procedure of [Shue \(2013\)](#) discussed in Section 4.3. The second section provides supplementary figures and tables.

***A. Residual Distances between Peers***

If peers influence a teacher’s refinancing decision through social interactions, teachers who share common off-periods should exhibit abnormally similar refinancing behavior relative to teachers with no overlap in off-periods. To test this premise, we follow the procedure of [Shue \(2013\)](#) and compare the mean absolute distance in residuals for the refinancing outcomes of overlapping versus non-overlapping teacher pairs. The estimation consists of the following steps:

*Step 1*— Obtain residuals for each teacher-month by estimating:

$$\mathbb{1}(Refi_{ijt}) = \alpha + BX_{it} + \tilde{r}_{it}, \tag{IA.A.1}$$

where  $\mathbb{1}(Refi_{ijt})$  is a 0/1 indicator for refinancing, and  $X_{it}$  represents controls for other determinants of refinancing, individual characteristics, peer characteristics, the commonality between teacher and peer characteristics, and campus-month controls. The residual  $\tilde{r}_{it}$  captures the unexplained component of refinancing. For teachers who own more than one property, we average the residuals at the teacher-month level.

*Step 2*— For all possible pairs of teachers in a campus-month, compute the following absolute distances among residuals:

$$Distance_{ijt} = \begin{bmatrix} |\tilde{r}_{it} - \tilde{r}_{jt-1}| \\ |\tilde{r}_{it} - \tilde{r}_{jt-2}| \\ |\tilde{r}_{it} - \tilde{r}_{jt-2}| \end{bmatrix}. \tag{IA.A.2}$$

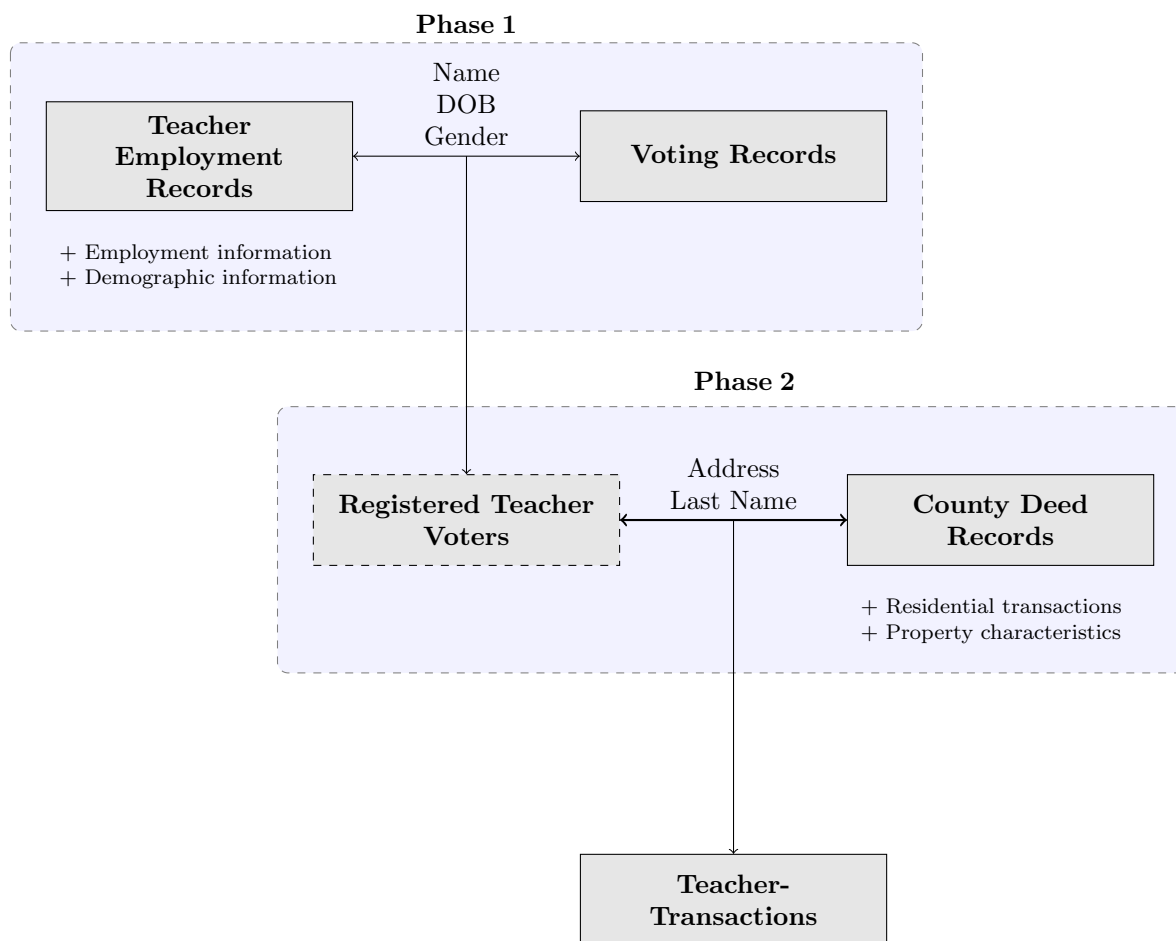

*Step 3*— Regress the absolute distances on a 0/1 indicator for whether the pair of teachers share common off-periods (i.e., the pair of teachers are classified as peers).

$$Distance_{ijt} = \alpha + \beta \mathbb{1}(Peer)_{ijt} + \epsilon_{ijt}. \tag{IA.A.3}$$

If  $\beta < 0$ , then peers sharing an off-period make more similar mortgage refinancing decisions than those with differing off-periods. Moreover the distance ratio  $\hat{\delta} = -\frac{\beta}{\alpha}$  quantifies the magnitude of the peer effect.

To evaluate the statistical significance of this result, we generate the distribution of each coefficient under the null of no peer effects, following [Shue \(2013\)](#). Specifically, we randomize the set of peers for each teacher-year observation while preserving the total number of peers for each observation. We assign this set of randomized peers to each monthly observation of the teacher-year, and re-estimate Step 3 ( $\beta_{random}$ ). A distribution under the null is formed by repeating this process 10,000 times for each specification. [Table IA.7](#) reports the  $p$ -values associated with the likelihood of  $\beta_{random}$  under the null hypothesis of randomized peer groups being less than the true coefficient  $\beta$  from Step 3.

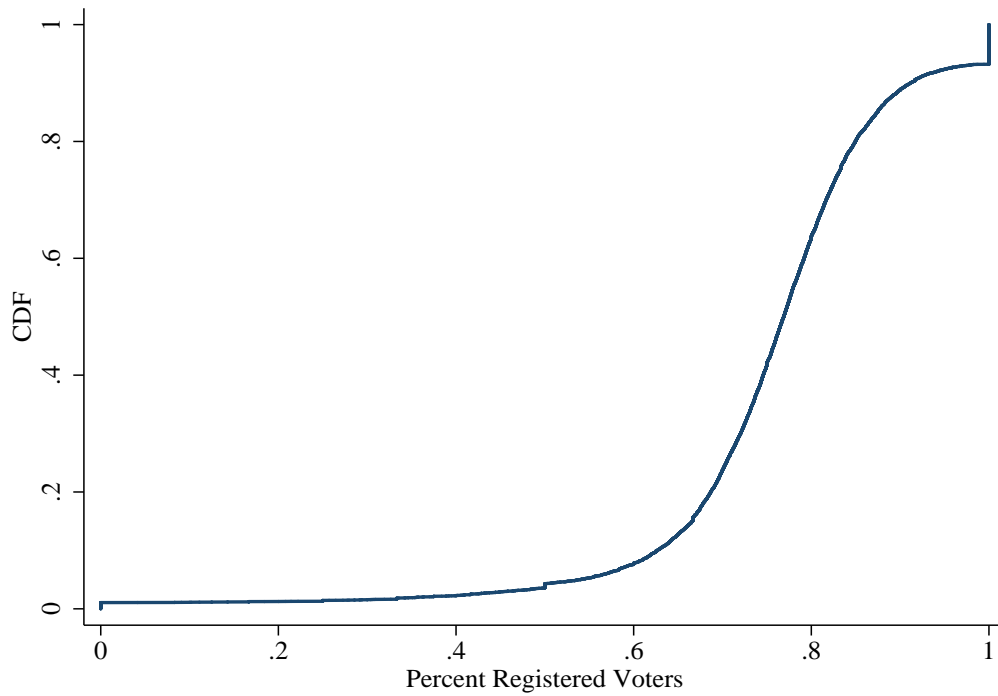

## B. Additional Tables and Figures

**Figure IA.1**  
**Data Matching Procedure**

This figure illustrates the process used to map teacher employment records to county deed records. First, the TEA payroll records are matched with the electoral records of registered voters based on name, date of birth, and gender, in order to obtain teachers' addresses (Phase 1). Then, we use these addresses and last names to match the resulting teacher voter records with county deed records (Phase 2). We require an exact match between the address number prefix, ZIP code, and individual's last name; we also require that the Levenshtein ratio between the address name listed on the county and voting records exceeds 0.9.

A: Registered voters per campus

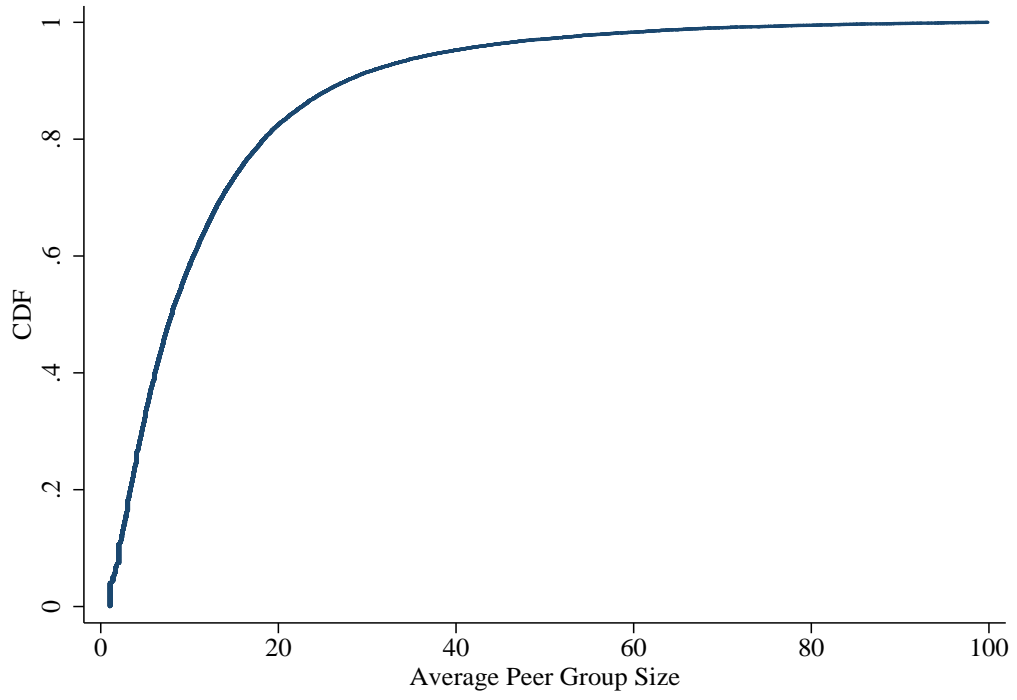

**Figure IA.2**

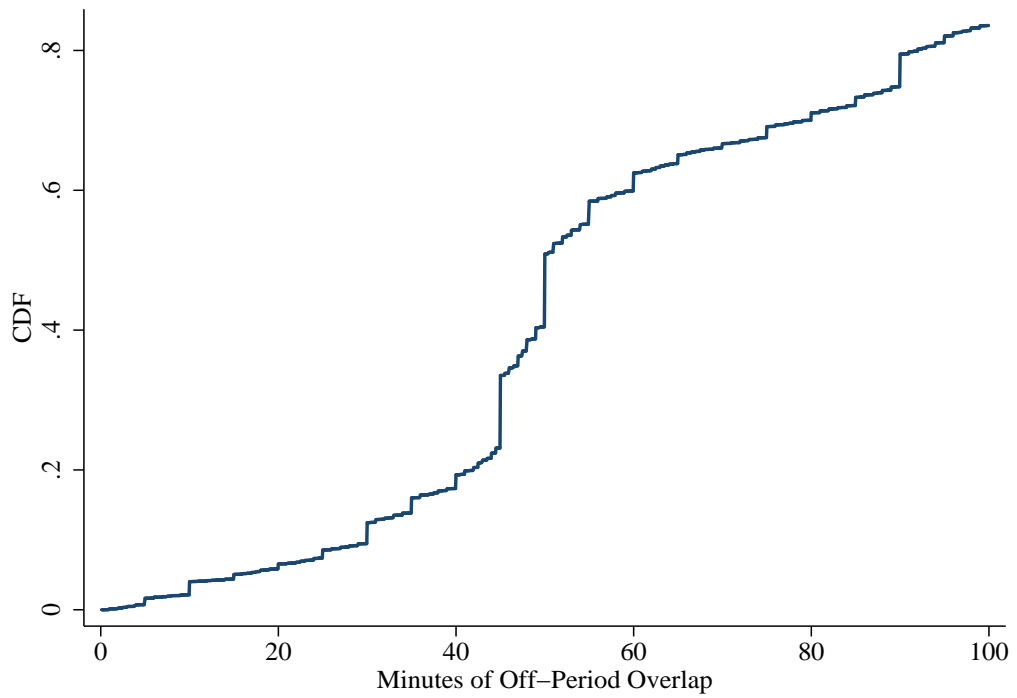

**Cumulative Distribution Functions**

This figure shows the cumulative distribution function (CDF) for the main variables considered in the sample selection process. Panel A shows the CDF for the percentage of registered voters per campus. Panel B shows the CDF for the average peer group size across campuses. Panel C shows the CDF for the number of minutes of off-period overlap across teachers. Panel D shows the CDF for the class length across campus-years.

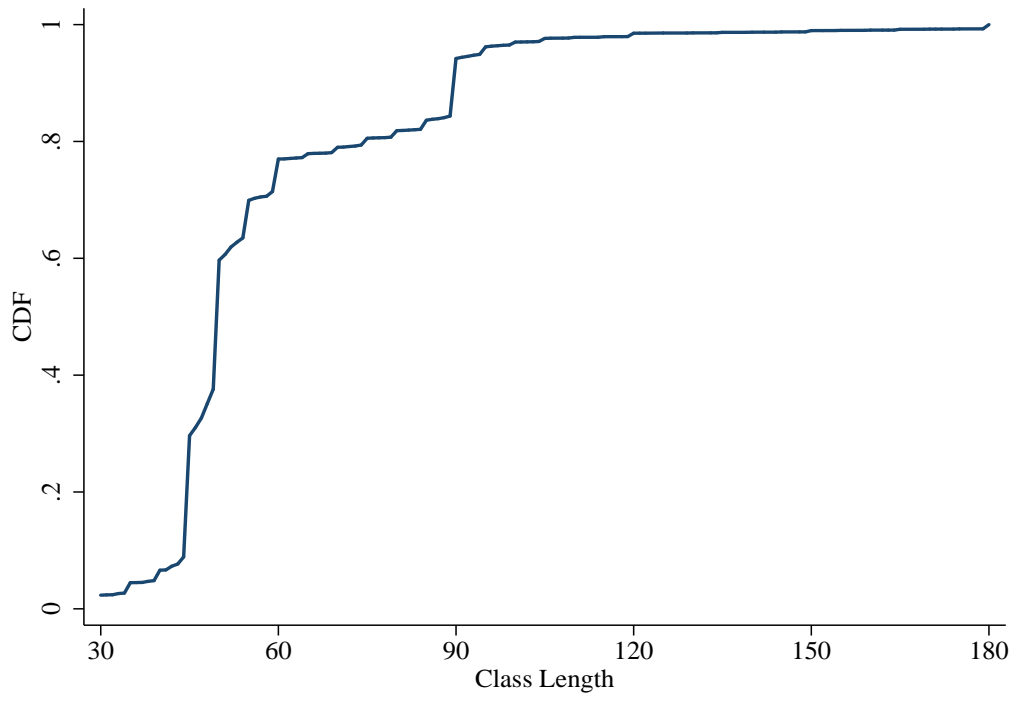

B: Average peer group size across campuses

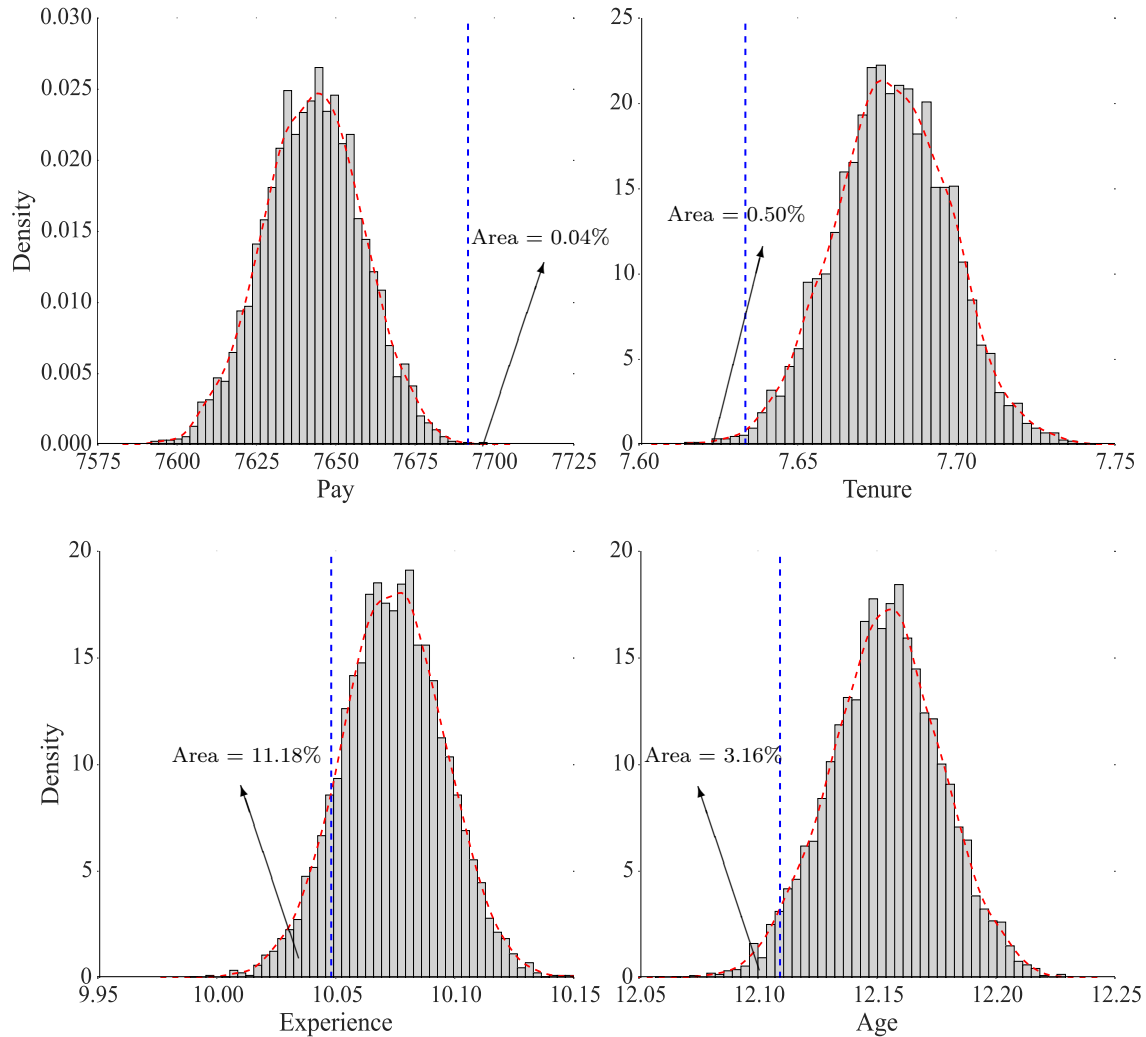

C: Number of minutes of off-period overlap across teachers

D: Class length across campus-years

**Figure IA.3**  
**Mean Absolute Difference with Peers**

This figure illustrates the degree of commonality for individual characteristics among peer groups relative to pseudo-peer groups. Commonality is defined as the mean absolute difference between a teacher and her peer group with respect to the characteristics considered: annual compensation (*Pay*), years of tenure at the current school (*Tenure*), total years of teaching experience (*Experience*), and current age as of September 1 of the current school year (*Age*). The observed degree of commonality in our peer groups are indicated by the dashed vertical blue line, while the histogram and kernel density estimate report the distribution of commonality from randomly generated peer groups. Each plot reports the percent of pseudo-peer groups falling further into the corresponding tail of the distribution. Pseudo-peer groups are formed by randomly drawing peers from the pool of all other individuals within a teacher's campus but outside her peer group.

<i>N (Districts)</i>	480	390	383	362	306	304	304	304	293	255	252

This table reports summary statistics for the sample through the progression of each sample selection restriction. Specifically, each column considers the sample: (1) before any filters are applied, (2) after dropping campus-years without Zillow coverage in the surrounding area, (3) after dropping campus-years with insufficient schedule data, (4) after dropping campus-years with a common off-period, (5) after dropping campuses without 70% registered voters, (6) after dropping campus-years in which the average peer group size makes up more than 75% of the total campus size, (7) after dropping campuses with an average peer group size of more than 50 teachers, (8) after dropping teachers who are not registered voters, (9) after dropping teacher-years not associated to a property record, (10) after dropping teachers who purchased or refinanced their homes using an adjustable-rate mortgage and teacher-years for which the savings of refinancing cannot be estimated, and (11) the final sample, after dropping teachers who purchase their homes prior to January 2001. The *t*-statistic from a difference-in-means test between the full population of teachers (in Column 1) and each restricted sample is reported in parentheses. \*\*\**p*<0.01, \*\**p*<0.05, \**p*<0.1.

<i>R</i> <sup>2</sup>	0.201	0.251	0.221

This table shows OLS regressions like those in Table 2 using alternate definitions for *Peer Refinances*. In Panel A, the number of peer refinances is scaled by the average peer group size of all teachers in the campus (instead of by peer group size). In Panel B, only refinances done by peers in the last two months are considered (instead of three months). In Panel C, *Peer Refinances* consists of a 0/1 indicator for peer refinancing in the trailing three-month period. Reported are the effects of a one standard deviation change in *Peer Refinances* for Panel A and Panel B. *t*-statistics in parentheses are heteroscedasticity-robust and clustered by MSA-year. \*\*\**p*<0.01, \*\**p*<0.05, \**p*<0.1.

This table shows hazard ratios of Cox Proportional Hazard model regressions in which the dependent variable is a 0/1 indicator of refinances, and the main variable of interest is *Peer Refinances*, a variable that captures the number of peers having undertaken a mortgage refinance in the previous 3-month period, scaled by the size of the peer group. Similar to the main analysis, the regressions include controls for other determinants of refinancing, teacher characteristics, and teacher-peer commonality. Depending on the specification, a campus-year refinancing index, a campus-month refinancing index, or time-slot controls are also included. Reported are the effects of a one standard deviation change in *Peer Refinances*, and *z*-statistics in parentheses are heteroscedasticity-robust and clustered by MSA-year. \*\*\**p*<0.01, \*\**p*<0.05, \**p*<0.1.

Peer Characteristics	yes	district $\times$ year	yes
Teacher-Peer Commonalities	yes	district $\times$ year	yes
Campus $\times$ Month FE	yes	yes	yes
Time Slot FE	no	no	district $\times$ year

This table shows the results of the multi-step procedure of [Shue \(2013\)](#). The details of the procedure are described in Internet Appendix A. A 0/1 indicator for refinancing is regressed on a set of determinants of refinancing, teacher characteristic controls, teacher-peer commonality controls, and campus-month fixed effects. *district  $\times$  year* denotes the interaction of district-year fixed effects with the corresponding control. The table reports the coefficients of the estimation of equation (IA.A.3), along with the distance ratio. The absolute distances in equation (IA.A.2) are regressed on a 0/1 indicator for common off-periods (i.e., peers). Reported *p*-values in parentheses are estimated by generating the distribution of each coefficient under the null of no peer effects, following [Shue \(2013\)](#). Specifically, the set of peers for each teacher-year observation are randomized while preserving the total number of peers for each observation. Then, we assign this set of randomized peers to each monthly observation of the teacher-year, and re-estimate equation (IA.A.3) ( $\beta_{random}$ ). A distribution under the null is formed by repeating this process 10,000 times for each specification. The *p*-values represent the likelihood of  $\beta_{random}$  under the null hypothesis of randomized peer groups being less than the true coefficient  $\beta$  from equation (IA.A.3). \*\*\**p*<0.01, \*\**p*<0.05, \**p*<0.1.

Teacher-Peer Commonalities	yes	district × year	yes
Campus × Month FE	yes	yes	yes
Time Slot FE	no	no	district × year
<i>N</i>	376,624	376,624	374,809
<i>R</i> <sup>2</sup>	0.608	0.669	0.650

This table reports the first stage of the 2SLS IV regressions of Table 3. Specifically, in Column 1 we estimate:

$$PeerRefinances_{ijt} = \beta PeerSavings_{ijt} + \gamma \mathbf{X}_{ijt} + \lambda \mathbf{W}_{ijt} + \eta \mathbf{Z}_{ijt} + \delta c(\mathbf{W}_{ijt}, \mathbf{Z}_{ijt}) + \phi_{jt} + \varepsilon_{ijt}.$$

The dependent variable, *Peer Refinances*, instrumented for in the second stage, is the number of a teacher's peers who have undertaken a mortgage refinance in the previous 3-month period, scaled by the size of the teacher's peer group. We use the average net savings conditional on refinancing of a teacher's peer group, *Peer Savings*, as an instrumental variable to estimate *Peer Refinances*.  $\mathbf{X}$  is a vector of other determinants of refinancing, such as the estimated savings of refinancing.  $\mathbf{W}$  is a vector of teacher characteristics;  $\mathbf{Z}$  is a vector of mean characteristics for a teacher's peer group;  $c(\mathbf{W}, \mathbf{Z})$  is a vector representing the commonality between  $\mathbf{W}$  and  $\mathbf{Z}$ . Finally,  $\phi_{jt}$  is a campus-month fixed effect. The variables *Peer Savings* and *Peer Refinances* have been standardized. Details for all variables are found in Data Appendix B. *district × year* denotes the interaction of district-year fixed effects with the corresponding control. Reported *t*-statistics in parentheses are heteroscedasticity-robust and clustered by MSA-year. \*\*\**p*<0.01, \*\**p*<0.05, \**p*<0.1.

**Table IA.9**

**Peer Effects on the Decision to Refinance: Subsamples Based on a Teacher’s Peers Average Savings**

Panel A: High peer savings

	(1)	(2)	(3)
Peer Refinances	20.766*** (4.75)	47.780*** (4.06)	31.042*** (5.19)
Savings (\$, ×10,000)	85.983*** (5.50)	115.517*** (4.60)	95.171*** (5.44)
1(Underwater)	-161.107*** (-9.64)	-178.986*** (-6.11)	-166.808*** (-8.76)
Percent Underwater	7.568 (0.04)	-454.608** (-2.03)	-112.740 (-0.52)
Loan Age (Months)	-6.626*** (-11.40)	-8.303*** (-9.87)	-7.108*** (-11.01)
Teacher Characteristics	yes	yes	yes
Peer Characteristics	yes	district × year	yes
Teacher-Peer Commonalities	yes	district × year	yes
Campus × Month FE	yes	yes	yes
Time Slot FE	no	no	district × year
<i>N</i>	130,702	130,702	130,296
<i>R</i> <sup>2</sup>	0.220	0.312	0.256

This table shows OLS regressions in which the dependent variable is a 0/1 indicator of refinances and the main variable of interest is *Peer Refinances*, a variable that captures the number of peers having undertaken a mortgage refinance in the previous 3-month period, scaled by the size of the peer group. The sample is divided into two mutually exclusive groups based on the median value of the teacher’s peers average savings. Panel A shows the estimation results in the subsample with the highest peer savings and Panel B shows the estimation results in the subsample with the lowest peer savings. Details for all variables are found in Data Appendix B. *district × year* denotes the interaction of district-year fixed effects with the corresponding control. Reported are the effects of a one standard deviation change in *Peer Refinances*, and *t*-statistics in parentheses are heteroscedasticity-robust and clustered by MSA-year. \*\*\**p*<0.01, \*\**p*<0.05, \**p*<0.1.

Panel B: Low peer savings

	(1)	(2)	(3)
Peer Refinances	1.831 (0.64)	14.886*** (3.07)	5.935 (1.26)
Savings (\$, $\times 10,000$ )	24.422** (2.19)	15.816 (0.97)	23.433** (2.03)
1(Underwater)	-69.065*** (-8.39)	-72.316*** (-4.89)	-65.476*** (-6.23)
Percent Underwater	-187.456* (-1.87)	-304.892** (-2.41)	-274.535*** (-3.20)
Loan Age (Months)	-3.213*** (-11.05)	-4.003*** (-8.99)	-3.457*** (-10.58)
Teacher Characteristics	yes	yes	yes
Peer Characteristics	yes	district $\times$ year	yes
Teacher-Peer Commonalities	yes	district $\times$ year	yes
Campus $\times$ Month FE	yes	yes	yes
Time Slot FE	no	no	district $\times$ year
